Diagnostic Accuracy of Fine Needle Aspiration Cytology in a Breast Lump Using Histopathology as Gold Standard

KHALID USMAN, BUSHRA NISAR*, MUHAMMAD SAJID**

ABSTRACT

Aim: To evaluate the diagnostic accuracy of fine needle aspiration cytology in a breast lump using histopathology as gold standard.

Study design: Cross sectional study.

Settings: Department of General Surgery, Bahawal Victoria Hospital, Bahawalpur.

Duration: From 10-03-2011 to 09-09-2011.

Results: Total 200 patients with breast lump were included in this study. Mean age of the patients was 35.45±8.57. All the patients were divided into different age groups. Ninety (45%) patients were in age group 20-30 years, 47 (23.5%) in age group 31-40 years, 32(16%) were in age group 41-50 years, 29(14.5%) were in age group 51-60 years and 2(1%) patients were in age group >60 years. Gender distribution was done and found 7(3.5%) male patients and 193(96.5%) female patients. Histopathological diagnosis of breast lesions show 53(26.5%) malignant and 147(73.5%) benign cases. Table 3 shows result of FNAC taking histopathology as gold standard. True positive (TP) were recorded as 49(24.5%), 16(8%) false positive (FP), 8(4%) false negative (FN) and 127(63.5%) as true negative (TN), sensitivity was 85.96%, specificity was 88.81%, positive predictive value (PPV) was 75.38% and negative predictive value (NPV) was 94.07%.

Conclusion: The evaluation of diagnostic accuracy of fine needle aspiration cytology in a breast lump using histopathology as gold standard shows a greater sensitivity and specificity, less invasive and cost effective procedure for the diagnosis.

Keywords: Breast lump, diagnostic accuracy, fine needle aspiration cytology

INTRODUCTION

Breast lumps are one of the most prevalent presenting complaints in an outpatient department (OPD) in Pakistan1. About 90% are benign and of no grave consequences, but malignant lumps contribute to a consequential percentage of all breast lumps. With growing vigilance in the general population, especially about breast pathologies, and the associated solicitude and stress that this condition may lead to, the knowledge that breast cancer can have grim consequences compels patients to seek medical advice2,3.

FNAC is an easily diagnostic method for determining the causes of a breast lesion. Its success is due to its accuracy and cost effectiveness for a breast lump. Therefore, it has many advantages for patients and physicians2. This study was conducted to determine the sensitivity and specificity of fine needle aspiration cytology (FNAC), by comparing the results with histopathology.

METHODOLOGY

Inclusion Criteria: All patients with lump in breast diagnosed clinically with any age and sex were included in the study. Patients with cellulites of breast, breast abscess and breast cysts were excluded from the study.

All patients coming through OPD fulfilling inclusion/exclusion criteria were included in the study. Patients with cellulites, abscesses and cysts were excluded to control confounding variables. The purposes, procedure, risks and benefits of this study were explained and informed consent was taken. After taking the history and examination fine needle aspiration cytology was performed under aseptic conditions by principle investigators having 3 years experience. Smear was sent to laboratory for cytology. Excision biopsy was done for small tumors or lump found benign on fine needle aspiration cytology and histopathology of mastectomy. Specimen will be included as tissue diagnosis. All the relevant information was filled on Performa.

Data was analyzed with the help of SPSS version 10.0 Mean±S.D. was presented for age of the patients. Frequencies and percentages were presented for gender distribution. A 2x2 table was used to determine the sensitivity, specificity, accuracy, positive and negative predictive value for
fine needle aspiration cytology taking histopathology as gold standard.

RESULTS
The detail of results is given in tables 1, 2, 3 & Fig. 1
Total 200 patients with breast lump were included in this study. Table 3 shows result of FNAC taking histopathology as gold standard. True positive (TP) were recorded as 49(24.5%), 16(8%) false positive (FP), 8(4%) false negative (FN) and 127(63.5%) as true negative (TN), sensitivity was 85.96%, specificity was 88.81%, positive predictive value (PPV) was 75.38% and negative predictive value (NPV) was 94.07%.

</tr>
</tbody>
</table>

Sensitivity = a / (a + c) x 100 = 85.96 %
Specificity = d / (d + b) x 100 = 88.81 %
Positive predictive value = a / (a + b) x 100 = 75.38 %
Negative predictive value = d / (d + c) x 100 = 94.07 %

DISCUSSION
Histopathological diagnosis of breast lesions in this study showed 53(26.5%) malignant lesions and 147(73.5%) as benign. Table 3 shows result of FNAC taking histopathology as gold standard. True positive (TP) were recorded as 49(24.5%), 16(8%) false positive (FP), 8(4%) false negative (FN) and 127(63.5%) as true negative (TN), sensitivity was 85.96%, specificity was 88.81%, positive predictive value (PPV) was 75.38% and negative predictive value (NPV) was 94.07%. Different studies have shown false positive results, ranging from 0-2% and false negative ranging from 7-22%

In one of the study performed at Khyber Teaching Hospital, Peshawar, Pakistan, from August 2002 to May 2003 the sensitivity and specificity of FNAC was 91.66% and 96.96%, respectively. There are some difficulties and limitations that need to be mention about FNAC, first at all, both false-negative and false-positive results can occur. Dysplasia also has a role in the false negative results. Small size of the tumors and certain histological types (lobular carcinoma, mucinous, tubular or medullary carcinoma) may contribute to false negative results. Fine needle aspiration cytology is the simplest method to evaluate breast lesions the results of this procedure are mostly dependent on the size of the lump, experience of the individual performing the procedure and the experience of the cytologist. FNAC has proven to be an effective diagnostic procedure in the evaluation of human breast lesions, and have a high degree of accuracy.

CONCLUSION
The sensitivity and specificity of fine needle aspiration cytology in this study was 85.96% and 88.81%. FNAC is recommended for the diagnosis of breast lumps, however before going for definitive treatment, tissue diagnosis is necessary as there have been cases of false negative results for FNAC.
