Assessment of Therapeutic Effects of Sofosbuvir Plus Ribavirin In Patients Suffering From Hepatitis C Virus With Genotype 3

KHALID MAHMUD KHAN1, TAUQEER AHMAD2, RANA MOZAMMIL SHAMSHER KHAN3, ANSAR LATIF4

ABSTRACT

Aim: This study was designed to assess response, safety and side effects of Sofosbuvir and Ribavirin in patients of HCV with genotype 3 infection.

Design: An open labeled study

Place and duration: Mayo Hospital Lahore and Liver clinic of Bahbhood Hospital, Lahore, department of medicine, KMSMC, Sialkot from October 2015 to February 2017.

Method: patients suffering from HCV infection were selected and their HCV- RNA was done by (Roche amplifier Switzerland). All patients were given Sofosbuvir 400mg daily and Ribavirin 800 -1200 mg in divided doses orally according to body weight for twenty four weeks. Followed up after 2 weeks and then at 04 interval. The patients undergoing study had baseline investigations of CBC, TSH, BSR, PCR quantitative for HCV RNA as well as genotype.

Result: Three hundred and twenty confirmed cases of chronic HCV(genotype 3) naïve patients were included. 180 (56.25%) male and 140 (43.75 %) female. Mean age of the patients was 45.66+10 years. After 2 weeks of treatment among 276 patients (86.25 %) positive response i.e.; undetectable HCV-RNA a very rapid virological response (VRVR) and at 4 weeks of treatment, rapid virological response (RVR) was seen among 302 patients (94.37%). 100% patients achieved early virological response (EVR) after 12 weeks, however 4 patients developed breakthrough i.e.; PCR was positive at the end of treatment. Among 316 patients who have attained end of treatment response, 40 patients (12.65%) developed relapse after 3 month of stopping therapy. Among 276 patients (86.25 %) 140 (43.75 %) male and 140 (43.75 %) female at 04 weeks had an undetectable level of serum HCV RNA.

Conclusion: This study supports that Sofosbuvir and Ribavirine has great efficacy, well tolerated regimen with a fewer side effect and can achieve SVR in patients suffering from chronic HCV.

Keywords: Hepatitis C. Sofosbuvir, Ribavirine. SVR.

INTRODUCTION

Hepatitis C is a chronic viral disease that varies in presentation from a silent disorder to a progressive inflammation of liver that may ultimately lead to cirrhosis, decompensated liver disease and hepatocellular carcinoma. HCV is a major burden of the resources of health in the hospitals and its effects on the society. In Pakistan the burden of this disease is increasing and is a great health problem. Its prevalence is very high despite the efforts to control viral infections. In certain regions of Pakistan the prevalence is as high as 16%. Hepatitis C is reported in 130 to 150 millions world population. In twenty percent of chronic Hepatitis C untreated patients cirrhosis may occur. About 300,000 to 350,000 hepatitis c virus related deaths are being reported each year. Therefore, it is recommended that with early treatment of Hepatitis C complications of cirrhosis and hepatic failure can be prevented. Eradication of virus may result in clinical improvement and regression of fibrosis. In Pakistan genotype 3 is common and response to Interferons about 70% to 80% Due to Interferons side effects most of patients of chronic hepatitis Care not willing to receive interferon based regimen. Therefore, oral treatment with Direct acting oral agents is being preferred for ch. hepatitis C.

Sofosbuvir is a direct-acting nucleotide polymerase inhibitor which has revolutionized the management of chronic hepatitis C. It has less adverse effects than Interferons. Sofosbuvir is an active nucleotide analogue that targets the HCV-specific NS5B polymerase. It acts as a non-obligate chain terminator and this effect is independent of the viral genotype. Lalezari J, et al. showed positive SVR (24) in 92 percent of genotype 2 or 3 patients (23 of 25 patients) after treatment with Sofosbuvir and Ribavirin. Edward J. Gane et al, conducted study in 50 HCV patients of untreated genotype 2 or 3 Hepatitis C patients, Sofosbuvir and Ribavirin for 12 weeks had an undetectable level of serum HCV RNA at 2,4,8,12,24, and 48 weeks. HCV Genotype 3 has
less rates of SVR and few drugs are effective in treatment of genotype 3\(^6\). Response rate for patients who have genotype 3 infection taking oral treatment is 80-85%, much less ascompared to genotype 1 or 2\(^7\).

There are very few studies reported from Pakistan indicating the efficacy and side effects of Sofosbuvir and Ribavirin treatment. The objective of this study was to assess the efficacy of the Sofosbuvir-based treatment in patients of HCV genotype 3 in Punjab, Pakistan.

MATERIAL AND METHODS

An open labeled multicentre study conducted at Liver clinic / South Medical Ward Mayo Hospital Lahore, Bahbood Hospital, Lahore and department of medicine at KMSMC, Sialkot conducted from October 2015 to February 2017.

One hundred and sixty patients, 90 male and 70 female between the age of 40-60 years were included. Information was given to all patients about events of the treatment, its side effects and outcome of treatment after informed written consent. Pregnant ladies, renal compromised patients, cardiac patients, patients of CCF and stroke or any major co-morbid condition were not included in this study. Hemoglobin of less than 10 g/dl, platelet count of 50,000/mm\(^3\) or less, ALT, AST and ALP 10 times or more and bilirubin level more than the upper normal limit, and creatinine clearance of less than 30 ml/min was used as an exclusion criteria. Patient who were suffering from HCV infection were selected and their HCV-RNA was done by (Roche reverse transcriptase) with lower limit of detection of 15 IU/ml were included after informed consent. Before starting therapy all baseline investigations CBC, LFT, serum Albumen, Urea, Creatinine, FBS, Lipid profile, Prothrombin Time (PT), APTT, TSH, and Genotype were done. An ultrasound of abdomen was done to see the evidence of cirrhosis on ultrasound abdomen.

All the patients with genotype 3 who fulfill inclusion criteria were enrolled in the study. Sofosbuvir was given 400 mg per oral daily along with Ribavirin 800-1200mg according to body weight. Ribavirin was given orally (800mg daily in patients with a body weight of <65 kg, 1000 mg daily in patients with a body weight of <75 kg, and 1200 mg daily in patients with a body weight of ≥75 kg). Initially patients were reviewed fortnightly and then every month. Treatment was continued for 24 weeks.

Patients followed up with CBC, LFTs t and RFTs. PCR for HCV-RNA was performed at week 2, 4, 12 weeks during the course of therapy. At the end of therapy PCR for HCV-RNA Qualitative was done to assess the end of treatment response (ETR). PCR for HCV-RNA Qualitative was done after 12 weeks of stopping treatment again to assess sustained virological response (SVR12). Patients with negative HCV RNA at the end of treatment and 12 weeks later were considered to achieve sustained viral response (SVR12), those with positive HCV RNA at the end of treatment were labeled as non-responders whereas those with negative PCR at the end of treatment but positive PCR after 12 weeks were labeled as relapsers. Data was analyzed by SPPS v 21.

RESULTS

Three hundred and twenty confirmed cases of chronic Hepatitis C were included in this study, 180 male (56.25%) and female 140 (43.75%) between the age 40-60 years. Patients showed good compliance. However, majority of patients had some decline in hemoglobin level, however 60 patients showed hemoglobin below 10 gm/dl. A drop of more than 3 g/dl seen and managed with Ribavirin dose adjustment, injection erythropoietin and iron supplementation, when required. Forty two patients showed rise in uric acid level. However 198 patients (61.87%) felt mild weakness and fatigue, 74 patients (23.13%) patients suffered from headache, 56 patients (17.5%) felt myalgia and arthralgia and cough was observed among 8.75% patients. 8 patient developed urticaria. Mild anxiety and depression was seen in 20 pts. All these abnormalities are shown in table- 1.

Response to therapy was seen after 2 weeks of treatment as recorded undetectable HCV-RNA a very rapid virological response (VRVR) among 276 patients (86.25%) and at 4 weeks of treatment, rapid virological response (RVR) was seen among 302 patients (94.37%). 100% patients achieved (EVR) after 12 weeks, however 4 patients who showed (VRV), RVR, and (EVR) developed breakthrough i.e., PCR was positive at weeks 24. Among 316 patients who have attained end of treatment response, 40 patients (12.65%) developed relapse after 3 month of...
stopping therapy, hence (SVR 12) was seen among 276 patients (87.34%) as shown in table 2.

DISCUSSION

Hepatitis C is a common cause of CLD in Pakistan and throughout the world and it is expected to increase many folds in next coming years due to its chronicity and mode of transmission. HCV infection has multiple risk factors and mostly the patients of HCV have non-specific symptoms. In different studies, patients with genotype 2 and 3 of HCV have SVR rates at 4 weeks ranging from 88 to 100%. In this study naïve patients of Chronic HCV and genotype 3 were treated and had early decline in HCV RNA levels. VRVR was seen in 86.25% patients, RVR among 94.37% patients and at the end of 12 weeks of treatment HCV RNA levels were not detected in all (100%) patients. This response was seen at the end of treatment in all except 4 patients who developed breakthrough i.e.; PCR was positive after the end of treatment. and SVR 12 was observed among 87.34%. These results are comparable to other published studies.

Study done by Sarwer S and Khan AA showed SVR12 86.2% (119/138) with Sofosbuvir / Ribavirin therapy in treatment naïve patients however it was 79.4% (54/68) in treatment experienced patients and difference was insignificant (p value 0.19). Edward J. Gene et All conducted a study in 50 naïve patients with HCV genotype 2 or 3 infection. All patients were treated withSofosbuvir and Ribavirin for duration of 12 weeks and undetectable level of serum HCV RNA at 2, 4, 8, 12, 24 and then at 48 weeks was seen. All patients had a positive SVR after 24 weeks of treatment.

According to Haroon Yousaf and colleagues reported 100% (847/847) response to Sofosbuvir and Ribavirin at the end of treatment (ETR) and 99.17% (840/847) SVR at 12 weeks of therapy. The rate of SVR was higher in previously treated patients (99.34%) as compared to naïve patients (97.80%). In previously untreated patients of HCV infection, resistance to protease and non nucleoside inhibitors are reported in more than 5% cases due to mutations in NS3 and NS5B regions. It is possible that in some cases relapses may occur after some time as Hepatitis C virus in lymphocytes, hepatocytes, macrophages remain undetectable. Some studies have supported that eradication of virus from the hepatocytes may result in to HCV-RNA undetectable up to 12 years. In another cohort patients after the end of therapy were followed for 18 years. HCV-RNA remained undetectable in serum but was detectable in biopsies of liver. In our study, Relapse rate was among 12.66 % patients with SVR 12 of 87.34% and results were comparable to other published studies.

This study shows the adverse effect profile of antiviral therapy was comparable with previous studies. Fatigue, headache, arthralgia, Epigastric discomfort, Cough, depression and insomnia were the most frequent adverse effects. Mild anxiety and depression and irritable behavior along with insomnia were also observed among significance number of patients. Hematological abnormalities seen were Hb<10gm% (n=37) 23.13%, Leucocytes count <4000 (n=105) 62.6% and Platelet count <100,000 (n=28) 17.5%. Adverse effects were mild to moderate, clinically manageable and all patients tolerated the side effects easily.

CONCLUSION

This study supports that Sofosbuvir and Ribavirin has greater efficacy, well tolerated regimen with a fewer side effect and can achieve SVR in majority of patients suffering from Chronic HepC Infection with genotype 3. Moreover, this study favors that Hepatitis C can be eliminated with this treatment from Pakistan.
